## ECE 245: Final Project

The pose of an individual robot is defined by the coordinates $[x, y, \theta]^{T}$, where $x$ and $y$ are the robot coordinates in a rectangular frame, and $\theta$ is the orientation angle with $\theta=0$ lying on the $x$-axis. The robot posture changes via the agent's on-board control loop, which defines the agent's linear acceleration $\dot{v}$ and angular velocity $\dot{\theta}$. The dynamic model of the robot used in this problem is given in a state space form as:

$$
\begin{gather*}
X(t)=\left[\begin{array}{l}
x_{1} \\
x_{2} \\
x_{3} \\
x_{4}
\end{array}\right], \quad F(X(t))=\left[\begin{array}{l}
f_{1} \\
f_{2} \\
f_{3} \\
f_{4}
\end{array}\right]=\left[\begin{array}{c}
v(t) \cos \theta(t) \\
v(t) \sin \theta(t) \\
0 \\
0
\end{array}\right]  \tag{1}\\
\dot{X}(t)=\left[\begin{array}{c}
\dot{x}_{1} \\
\dot{x}_{2} \\
\dot{x}_{3} \\
\dot{x}_{4}
\end{array}\right]=\left[\begin{array}{c}
v(t) \cos \theta(t) \\
v(t) \sin \theta(t) \\
0 \\
0
\end{array}\right]+\left[\begin{array}{c}
0 \\
0 \\
\xi_{v}(t) \\
\xi_{\theta}(t)
\end{array}\right] \tag{2}
\end{gather*}
$$

The knowledge of the control inputs $\dot{v}$ and $\dot{\theta}$ would greatly decrease the error in the pose estimation. In many cases, the control inputs are unknown to an external observer. For this reason, the control variables $\dot{v}$ and $\dot{\theta}$ are modeled with the zero-mean white noises $\xi_{v}(t)$ and $\xi_{\theta}$, respectively. Measurements provided by the camera are absolute position measurements $x_{m}$ and $y_{m}$ assumed to include the zero-mean Gaussian-distributed noise $w_{x} \sim N\left(0, W_{x}\right)$ and $w_{y} \sim N\left(0, W_{y}\right)$. This measurement model is defined as:

$$
Z(t)=\left[\begin{array}{l}
x_{m}(t)  \tag{3}\\
y_{m}(t)
\end{array}\right]=\left[\begin{array}{llll}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0
\end{array}\right] X(t)+\left[\begin{array}{l}
w_{x} \\
w_{y}
\end{array}\right]
$$

We utilize stochastic signals as a general model of the unknown control signals. The advantage of modeling the unknown control signals as stochastic signals is that we can exploit the Kalman filter theory to estimate unknown speed $v$ and angle $\theta$ based only on the position measurements $x_{m}$ and $y_{m}$.

Estimate the velocity $v(k)$ and angle $\theta(k)$ of the robot from the movie "Final.mov" using EKF and second order filter (SOF) based on the discrete time model of (1)-(3). The angle $\theta$ should be estimated in the range $(-\pi, \pi]$. The data for your estimations are coordinates of the robot center $x_{m}(k)$ and $y_{m}(k)$ are converted in cm and provided in "XYData_cm.csv" for every 10th frame of the movie. The movie has been recorded with the rate of 30 frames per second. Each coordinate was found as a center of the equilateral triangle formed by the three red lights. Compare results of the EKF and SOF.

Obviously, the triangle can help you estimate the angle $\theta(k)$ without any filter; let us call that estimation $\alpha(k)$. The angle $\alpha(k)$ is provided in "HeadingAngle_rad.csv" and can be considered as a true value of the angle $\theta(k)$. Compare the value of $\alpha$ with $\hat{\theta}$, which is the angle estimation resulting from
your filters. You will likely need to go through the process of filter designs and comparison couple of times until you find that filters produce reasonable results.

Make a several-page report in which you will explain your derivations and choices for the initial state, all covariance matrices, and plot representative diagrams including tha data extracted from the movie.

Remark: The data are derived from the movie based on the following information: (1) the image resolution is $320 \times 240$; (2) the robot size is about 70 mm in diameter; (3) the distance from the front light to the both back lights is 61 mm ; and (4) the distance between the two back lights is 46 mm . While you do not need to extract the data from the movie, you still need these information to figure out what is the measurement noise in measuring the robot position. You will likely need to try various values for the process noisy intensity.
